Introduction to Survival Analysis

Thomas Hielscher (t.hielscher@dkfz.de)
Div. of Biostatistics

Kaplan Meier method and log-rank test

1 Characteristics of survival data

2 Survival function

3 Comparison of survival curves

4 Using SigmaPlot

5 Other Topics

Survival endpoint

- Response of interest: time to event (failure time, survival time, event time)

Examples:

- Time from to start of therapy to death
- Time from surgery to tumor recurrence

State the event, start and end of the period

- Endpoint may not be observed

Examples:

- End of study before all patients had relevant outcome (incomplete follow-up)
- Relocation (lost to follow-up)
- Death from other cause (different outcome)

→ Incomplete responses are (right-)censored

→ Different methods for analysis and visualisation required

Censoring

Types of (right-)censoring

- Fixed type I censoring: study ends after a pre-specified follow-up time for each subject (e.g. animal experiments)
- Random type I censoring: study ends at a pre-specified time point (e.g. cut-off date in clinical study)
- Type II censoring: study ends after pre-specified number of events are observed

Fundamental Principle: Mechanism of censoring is independent (non-informative) of the mechanism of failure

Examples for dependent censoring:

- death from other cause (competing risk)
- drop-out due to drug-toxicity

Example data

Data from Freireich et al., "The effect of 6-mercaptopurine on the duration of steroid-induced remissions in acute leukemia" Blood 21, 699-716, 1963.

| patient | time | relapse |
|---------|------|---------|
| A | 6 | yes |
| B | 10 | no |
| C | 23 | yes |
| D | 25 | no |

Survival time is not calendar time

Survival data

- T_i denotes survival time of subject i , $i = 1, \dots, N$
- C_i denotes censoring time of subject i
- The observed response is $Y_i = \min(T_i, C_i)$
- δ_i denotes the event indicator: 1 if $T_i \leq C_i$, 0 if $T_i > C_i$

| patient | i | T_i | C_i | Y_i | δ_i |
|---------|----------|-------|-------|-------|------------|
| A | 1 | 6 | | 6 | 1 |
| B | 2 | | 10 | 10 | 0 |
| | \vdots | | | | |

Risk set

Example data, treatment group only (n=21):

n_t denotes number of patients at risk at time t , i.e. $Y_i \geq t$

| time | patients at risk n_t | relapse d | censoring c |
|------|------------------------|-------------|---------------|
| 6 | 21 | 3 | 1 |
| 7 | 17 | 1 | 0 |
| 8 | 16 | 0 | 0 |
| 9 | 16 | 0 | 1 |
| ⋮ | | | |

Theoretical survival function

- T denotes the survival time, $T \geq 0$
- $F(t)$: distribution function of the survival times T
- Survival function $S(t) = Pr(T > t) = 1 - F(t)$

- $S(t)$ gives the probability that a subject survives past time t
- $S(t)$ is non-increasing
- $S(0) = 1$
- $S(\infty) = 0$ (exception e.g. cure rate models)
- Only in theory smooth $S(t)$, in practice time scale discrete (days, weeks,..)

Estimation of the survival function

- parametric methods: assumptions on the distribution of T (e.g. Weibull, exponential, log-normal)
 - AFT regression models
- semi-parametric methods: assumption on relative effects over time
 - Cox PH model (see lecture next week)
- non-parametric methods: no assumption on distribution of T
 - Kaplan-Meier method
 - Log-rank test

Kaplan-Meier method (1)

- Probability to survive past t is estimated as proportion of patients being alive at t among patients at risk
- Concept of conditional probabilities: in order to survive timepoint t , you have to survive timepoint $t - 1$

Kaplan-Meier method (2)

Idea of conditional probabilities:

p_1 = probability of surviving the first day ($S(1) = p_1$)

p_2 = probability of surviving the second day, given one has survived day 1 (conditional probability)

→ (unconditional) probability of surviving day 2 is $S(2) = p_1 \times p_2$

Generalizes to:

$$\begin{aligned} S(t) &= S(t-1) \times p_t \\ &= p_1 \times p_2 \times \dots \times p_{t-1} \times p_t \end{aligned}$$

Kaplan-Meier method (3)

Estimation of survival probability p_t :

- no failure, no censoring at timepoint t :

$$\hat{p}_t = \frac{n_t - 0}{n_t} = 1, n_{t+1} = n_t$$

estimated survival probability $\hat{S}(t) = \hat{S}(t-1)$

- d failures at timepoint t , $d \geq 1$:

$$\hat{p}_t = \frac{n_t - d}{n_t} < 1, n_{t+1} = n_t - d$$

$\hat{S}(t)$ drops since $\hat{S}(t) = \hat{S}(t-1) \times \hat{p}_t$, patients at risk decrease

- c censorings at timepoint t , $c \geq 1$:

$$\hat{p}_t = \frac{n_t - 0}{n_t} = 1, n_{t+1} = n_t - c$$

$\hat{S}(t)$ remains constant, patients at risk decrease

Kaplan-Meier method (4)

Kaplan Meier estimator:

$$\hat{S}(t) = \prod_t \hat{p}_t = \hat{p}_1 \times \hat{p}_2 \times \dots \times \hat{p}_{t-1} \times \hat{p}_t = \prod_t \frac{n_t - d}{n_t}$$

- Also called: product limit estimate
- Unbiased under non-informative censoring
- In absence of censoring, KM estimator reduces to binomial estimate
- Variance estimation (Greenwood's formula):

$$\hat{V}[\hat{S}(t)] = \hat{S}(t)^2 \sum_t \frac{d}{n_t(n_t - d)}$$

Example data

Kaplan-Meier Plot – Treatment group only (N=21)

| t | risk | d | c | \hat{p}_t | $\hat{S}(t)$ |
|-----|------|-----|-----|---------------------|--------------|
| 6 | 21 | 3 | 1 | $\frac{21-3}{21} =$ | 0.86 0.86 |
| 7 | 17 | 1 | 0 | $\frac{17-1}{17} =$ | 0.94 0.81 |
| 9 | 16 | 0 | 1 | $\frac{16-0}{16} =$ | 1.00 0.81 |
| 10 | 15 | 1 | 1 | $\frac{15-1}{15} =$ | 0.93 0.75 |
| 11 | 13 | 0 | 1 | $\frac{13-0}{13} =$ | 1.00 0.75 |
| 13 | 12 | 1 | 0 | $\frac{12-1}{12} =$ | 0.92 0.69 |
| 16 | 11 | 1 | 0 | $\frac{11-1}{11} =$ | 0.91 0.63 |
| 17 | 10 | 0 | 1 | $\frac{10-0}{10} =$ | 1.00 0.63 |
| 19 | 9 | 0 | 1 | $\frac{9-0}{9} =$ | 1.00 0.63 |
| 20 | 8 | 0 | 1 | $\frac{8-0}{8} =$ | 1.00 0.63 |
| 22 | 7 | 1 | 0 | $\frac{7-1}{7} =$ | 0.86 0.54 |
| 23 | 6 | 1 | 0 | $\frac{6-1}{6} =$ | 0.83 0.45 |
| 25 | 5 | 0 | 1 | $\frac{5-0}{5} =$ | 1.00 0.45 |
| 32 | 4 | 0 | 2 | $\frac{4-0}{4} =$ | 1.00 0.45 |
| 34 | 2 | 0 | 1 | $\frac{2-0}{2} =$ | 1.00 0.45 |
| 35 | 1 | 0 | 1 | $\frac{1-0}{1} =$ | 1.00 0.45 |

Median survival time

Kaplan–Meier Plot

- Timepoint where $\hat{S}(t) = 0.5$
- Not always observed/inaccurate due to few patients at risk
- Confidence interval

Survival rate

Survival probability at timepoint t :

Kaplan–Meier Plot

- Use standard time points (e.g. 1 year, ...)
- Confidence interval

Median follow-up

Censoring distribution (KM)

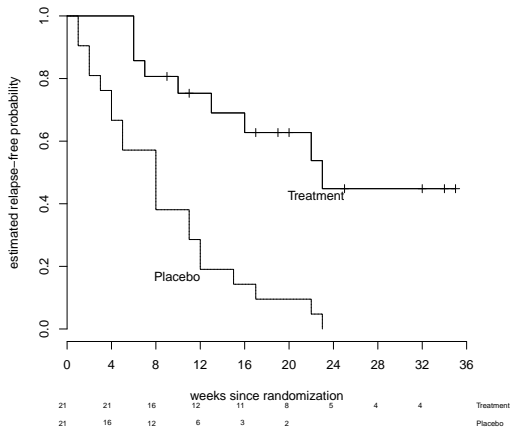

- Switch event indicator: $1 - \delta_i$ (Korn, 1986)
- Estimated censoring distribution
- Timepoint where $\hat{S}(t) = 0.5$

Mean survival time

- Generally: do not report simple mean survival time from $\hat{S}(t)$
 - area under the survival curve
 - not defined if last observation is censored, i.e., survival curve does not go to zero
 - groups not comparable if maximum observed time are different
- Restricted mean survival time (RMST):
 - average survival from time 0 to a specified time point t_{max}
 - t_{max} observed in all groups/curves
 - estimated as the area under the survival curve up to that point t_{max}
 - groups can only be compared for the same t_{max}

Example data

Kaplan–Meier Plot

log-rank test (1)

- Mantel-Haenszel/Mantel Cox test
- Non-parametric test
- Null hypothesis H_0 : there is no difference between the populations in the probability of an event at any time point
- Idea: describe survival process with a series of time-dependent 2×2 contingency tables, one for each event time $t_{(j)}$
- Compare observed vs. expected number of events at each time point

log-rank test (2)

| group | events at $t_{(j)}$ | no event at $t_{(j)}$ | at risk at $t_{(j)}$ |
|--------|---------------------|-----------------------|----------------------|
| A | d_{Aj} | $n_{Aj} - d_{Aj}$ | n_{Aj} |
| B | d_{Bj} | $n_{Bj} - d_{Bj}$ | n_{Bj} |
| Totals | d_j | $n_j - d_j$ | n_j |

- One table for each event time $t_{(j)}$, $j = 1, \dots, m$
- Under H_0 of no difference:
expected number of events at $t_{(j)}$ in group A is $\hat{e}_{Aj} = \frac{d_j n_{Aj}}{n_j}$
- Test statistic: $Q = \frac{(\sum d_{Aj} - \sum \hat{e}_{Aj})^2}{\sum \hat{V}(\hat{e}_{Aj})}$
- Variance of \hat{e}_{Aj} is $\hat{V}(\hat{e}_{Aj}) = \frac{n_{Aj} n_{Bj} d_j (n_j - d_j)}{n_j^2 (n_j - 1)}$
- Q is asy. χ_1^2 distributed under H_0

Example data

| j | $t_{(j)}$ | n_{Aj} | d_{Aj} | n_{Bj} | d_{Bj} | \hat{e}_{Aj} | $\hat{V}(\hat{e}_{Aj})$ |
|-------|-----------|----------|----------|----------|----------|----------------|-------------------------|
| 1 | 1 | 21 | 0 | 21 | 2 | 1.00 | 0.49 |
| 2 | 2 | 21 | 0 | 19 | 2 | 1.05 | 0.49 |
| 3 | 3 | 21 | 0 | 17 | 1 | 0.55 | 0.25 |
| 4 | 4 | 21 | 0 | 16 | 2 | 1.14 | 0.48 |
| 5 | 5 | 21 | 0 | 14 | 2 | 1.20 | 0.47 |
| 6 | 6 | 21 | 3 | 12 | 0 | 1.91 | 0.65 |
| 7 | 7 | 17 | 1 | 12 | 0 | 0.59 | 0.24 |
| 8 | 8 | 16 | 0 | 12 | 4 | 2.29 | 0.87 |
| 9 | 10 | 15 | 1 | 8 | 0 | 0.65 | 0.23 |
| 10 | 11 | 13 | 0 | 8 | 2 | 1.24 | 0.45 |
| 11 | 12 | 12 | 0 | 6 | 2 | 1.33 | 0.42 |
| 12 | 13 | 12 | 1 | 4 | 0 | 0.75 | 0.19 |
| 13 | 15 | 11 | 0 | 4 | 1 | 0.73 | 0.20 |
| 14 | 16 | 11 | 1 | 3 | 0 | 0.79 | 0.17 |
| 15 | 17 | 10 | 0 | 3 | 1 | 0.77 | 0.18 |
| 16 | 22 | 7 | 1 | 2 | 1 | 1.56 | 0.30 |
| 17 | 23 | 6 | 1 | 1 | 1 | 1.71 | 0.20 |
| Total | | | 9 | | 21 | 19.25 | 6.26 |

- $t(j) = 1$

| group | events | no event | at risk |
|--------|--------|----------|---------|
| A | 0 | 21 | 21 |
| B | 2 | 19 | 21 |
| Totals | 2 | 40 | 42 |

- $Q = (9 - 19.25)^2 / 6.26 = 16.79$
- p-value:
 $1 - P(Q \geq 16.79 | H_0) < 0.001$

Properties/assumptions of log-rank test

- Independence of censoring required
- Can be generalized to more than two groups:
global null hypothesis vs. trend test
- Not appropriated for crossing survival curves (see numerator of Q)
- Weights within Q can be defined to derive different tests
- Gives equal weights to all time points
- Optimal power in case of proportional hazards → next week
- Provides no effect size → Regression model

Gehan-Wilcoxon test

- Gehan-Breslow (SigmaPlot), generalized Wilcoxon
- Same class of tests as log-rank test
- Time points are weighted based on number at risk
- More weight on earlier events, detects differences early in time
- (Sometimes) more powerful if proportional hazard assumptions does not hold → next week
- Equivalent to Wilcoxon rank sum test in case of no censoring

Stratified log-rank test

- Control for effect of additional categorical variable/confounder
- Split data into subgroups (strata)
- Calculate numerator/denominator of Q in each subgroup and average across subgroups
- Too small strata/subgroups affect power
- No estimation of effect of stratified variable (Regression model)
- Not implemented in SigmaPlot/GraphPad Prism

Log-rank test using SigmaPlot? (2)

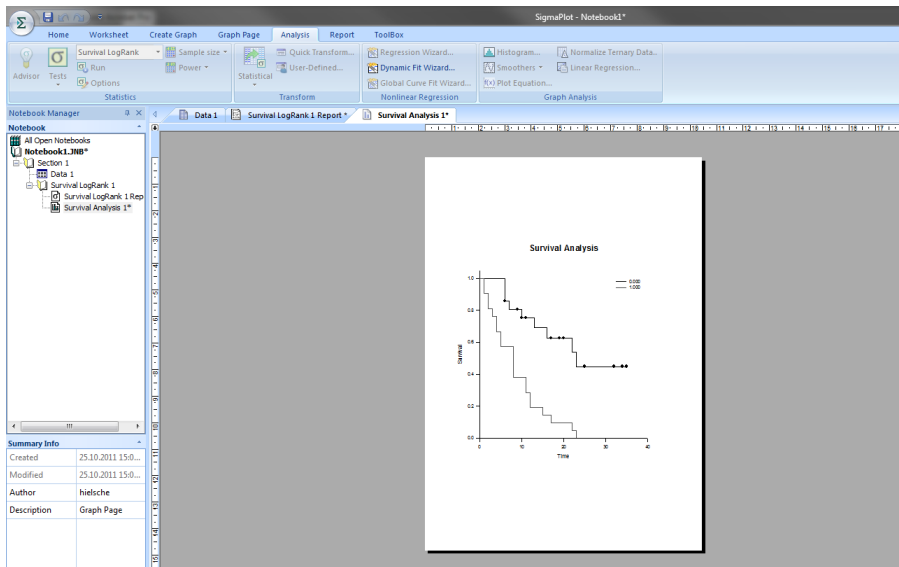

The screenshot shows the SigmaPlot software interface with a worksheet titled 'Data 1' containing survival data. A dialog box titled 'Survival LogRank - Select Data' is open, allowing the user to select data for a log-rank test. The dialog box has a section for 'Select data by clicking worksheet columns.' and a list of data points with columns for '1-time', '2-Status', and '3-group'. The 'Data for Status' dropdown is set to '2-status'. The 'Selected Columns' list includes 'Group: 3-group', 'Time: 1-time', and 'Status: 2-status'.

| | 1-time | 2-status | 3-group |
|----|--------|----------|---------|
| 1 | 35 | 0 | 0 |
| 2 | 34 | 0 | 0 |
| 3 | 32 | 0 | 0 |
| 4 | 32 | 0 | 0 |
| 5 | 25 | 0 | 0 |
| 6 | 23 | 1 | 0 |
| 7 | 22 | 1 | 0 |
| 8 | 20 | 0 | 0 |
| 9 | 19 | 0 | 0 |
| 10 | 17 | 0 | 0 |

Log-rank test using SigmaPlot? (3)

Log-rank test using SigmaPlot? (4)

Time-dependent covariates - 'immortal bias'

- Group assignment not known at start of time interval
endpoint: time from therapy start to death
covariates: response to treatment, transplantation, etc.
- If covariate is treated as if known in advance → biased estimates
- E.g. response to treatment: responders must live long enough for response to be observed; there is no such requirement for nonresponders.

Solution:

- Landmark analysis
- Methods to account for time-dependent variables (Simon-Makuch, Cox regression)

Categorization of continuous predictors

Issues:

- loss of power in case there is no real dichotomy: split at median is like discarding a third of the data
- choice of cutpoint
- generalization/validation of cutpoint

How to dichotomize?

- a priori known cutpoint
- distribution parameter (e.g. median): arbitrary
- optimal cutpoint: optimal discrimination w/r/t response, biased estimates/p-values due to type I error inflation

Power and Sample Size

- Number of events **not** number of subjects provides power:
required events = $\frac{4 \cdot (z_{\alpha} + z_{\beta})^2}{(\log(\text{HazardRatio}))^2}$,
for exponentially distributed survival times
- More events can be observed with
 - more subjects
 - longer follow-up
 - combined/early endpoints (PFS vs. OS)
 - prognostically selected population
